

Q9 - Which method on the session object can be used to remove an object from the cache?

Ans- The **evict(Object object)** method of the Hibernate Session object is used to remove a specific object from the first-level cache.

Q10 - What does @transactional annotation do?

Ans--The @Transactional annotation in Spring manages database transactions in a straightforward way. When you annotate a method or class with @Transactional, Spring starts a transaction before the method runs. It commits the transaction after the method finishes successfully. If a runtime exception happens during execution, the transaction rolls back to keep the data consistent. This annotation helps ensure that operations are atomic and consistent without needing manual transaction handling in the code.
